| -\\s | Surface-e | enhanced Ram | an scattering | (SERS) wa | s used for | · charact | erization | |
| Surface-enhanced Raman scattering (SERS) was used for characterization of model fiber/polyimide interfaces. Pyromellitic diimide (PMDI) was used | | | | | | | | |
| as a model polyimide while highly oriented pyrolytic graphite (HOPG) was | | | | | | | | |
| viewed as a model graphite fiber. Samples for SERS were prepared by deposit- | | | | | | | | |
| ing films of PMDI onto HOPG and then depositing silver island films on top of | | | | | | | | |
| the PMDI. When the PMDI films were relatively thick (85 A), the SERS | | | | | | | | |

19. Abstract (continued)

band due to a CNC axial stretching vibration and the 1200 cm⁻¹ band due to a CNC axial stretching vibration and the 1200 cm⁻¹ band due to a CX in-plane stretching mode were strong. Differences in the relative intensities of bands in the SERS spectra were attributed to orientation effects. It was concluded that PMDI films deposited on HOPG were actually bilayers in which the molecules adjacent to the surface were adsorbed with a vertical conformation in which the planes of the molecules were perpendicular to the surface and one imide group was in contact with the surface. Molecules farther away from the surface had a random orientation.
